Litigation as a Measure of Well-Being

Theodore Eisenberg, Sital Kalantry, and Nick Robinson*

Abstract

The common perception is that high or growing litigation rates in a country are a sign of societal pathology. Studies of litigation rates, however, consistently report that lawsuit filings per capita increase with economic prosperity, thus suggesting that litigation rates are a natural consequence of prosperity and not necessarily evidence of an overly litigious populace. India's substantial interstate variation in litigation rates and in economic and noneconomic measures of well-being provide an opportunity to evaluate the relation between well-being and litigation rates. Using many years of data on civil filings in India's lower courts and High Courts, we present evidence that more prosperous states have higher civil litigation rates. We also report the first evidence that accounting for noneconomic well-being, as measured by the education and life expectancy components of the Human Development Index, explains litigation rate patterns better than using a purely economic measure of well-being, GDP per capita. Despite India's continuing economic growth, we present data that indicates India's enormous and growing civil case backlog has discouraged civil case filings in recent years. These findings raise the question whether India's future economic growth will be compromised if courts at all levels, particularly lower courts, do not resolve disputes more quickly.

Keywords: litigation, well being, India

JEL Classification: K41, K49, P59

* Eisenberg is Henry Allen Mark Professor of Law and Adjunct Professor of Statistical Sciences, Cornell University; Kalantry is Clinical Professor, Cornell Law School and a Fulbright-Nehru Senior Research Scholar and Visiting Professor at Jindal Global Law School (Spring 2012); Robinson is a visiting fellow at the Centre for Policy Research, New Delhi.

In the United States portraying much litigation as pathological is a key component of business lobbying groups' social construction of the legal system.¹ They commission and use questionable social science analysis² and misleadingly portray highly publicized cases, such as the McDonald's coffee spill case.³ They do so to help characterize civil litigation as dominated by lottery-seeking plaintiffs, greedy plaintiff's lawyers, and state civil justice systems that are too hostile to business. Marc Galanter and others have refuted these myths⁴ but they persist even among well-informed observers.⁵ Debunking misleading litigation anecdotes is necessary and important. The need to defend against unwarranted attacks on litigation, however, should not distract from studying litigation's important institutional role in society. Notwithstanding the U.S. corporate assault on litigation, law and development scholars have long viewed increased litigation as a natural attribute of increasing prosperity.⁶

This empirical study of litigation in India supplies substantial new evidence that higher litigation rates are not necessarily evidence of an overly litigious society or a drain on the economy; they can be a natural consequence of economic development and improved human well-being. In India, more prosperous states have for decades had higher litigation rates than less prosperous states. And at least in recent years, so have states with higher levels of urbanization. We also report the first evidence that accounting for economic and noneconomic well-being together, as measured by the Human Development Index (HDI), seems to explain litigation rate patterns better than explanations limited only to economic measures of well-being, such as GDP per capita, or only to noneconomic measures such as literacy rates.

Surprisingly, however, states that have prospered more do not show increased within-state civil litigation rates in recent years. We present evidence that India's enormous case backlog may be deterring potential litigants from filing claims. This raises the question whether Indian economic growth can be sustained without the well-functioning courts that some regard as an institutional requisite to robust economic performance and human well-being.⁷

Focusing on both India and litigation rates using empirical methodology is particularly appropriate as part of this Symposium honoring Professor Marc Galanter's work. His interest in India's legal system⁸ complements his path breaking work on the U.S. legal system. And he has long used empirical evidence to describe legal systems' operations and held the view that popular opinion about litigation rates in the United States⁹ and India is misplaced. Indians have long been branded as abnormally litigious and Galanter was an early user of data to refute this assertion.¹⁰ Although comparing studies of litigation rates across countries presents challenges, India's litigation rate appears to be comparatively low,¹¹ and may even be lower than it was in the nineteenth century or the first half of the twentieth century.¹² We build on this theme of Galanter's work and extend it. By emphasizing the relation between civil litigation rates and improved human well-being, we challenge the dogma that increasing litigation rates should be regarded as evidence of a malfunctioning society.¹³

I. The Relation Between Litigation and Development

Thoughtful assessments of the relation between litigation rates and economic prosperity have long hypothesized that, at least in early stages of economic development, increasing litigation rates should be associated with increasing economic development.¹⁴ "Increased reliance on formal law and its processes appears to parallel changes in the complexity of a society which are produced by economic growth and development."¹⁵ This parallel change observation effectively hypothesizes a positive association between litigation rates and prosperity. Professor Galanter's early work on litigation provided information about one possible source of the association. He assembled studies to support the claim that data "from a variety of courts suggest that plaintiffs are predominantly business or governmental units . . ."¹⁶ Economic growth, it is reasonable to assume, manifests itself in part in more businesses and more governmental activity and, presumably, greater litigation activity by those entities. The data included studies from Germany and Great Britain,¹⁷ suggesting that the association is not unique to the United States.

¹² Oliver Mendelsohn, *The Pathology of the Indian Legal System*, 15 *Mod. Asian Stud.* 823, 849 (1981).

¹³ Our claims are limited to civil litigation rates. Counter-intuitively, high criminal litigation rates might also be connected to improved well-being as more economically developed societies may institutionalize the prosecution of crime more. However, higher criminal litigation is also seemingly correlated with higher crime rates in absolute terms, which would indicate a weakening of social well-being. Exploring these details is beyond the scope of this paper.

Other data support the association between economic prosperity and litigation. Wollschläger in 1998 reported on civil litigation rates for 35 countries.¹⁸ The data were not available for each country for the same year so the litigation data ranged from 1987 to 1996. He observed that low litigation rates in Ethiopia, Nepal, Paraguay, and the Solomon Islands “can easily be attributed to economic underdevelopment”¹⁹ but he provided no statistical analysis comparing litigation rates with economic development. Data analyzed by Jacobi about U.S. states detected a positive association between litigation rates and a strong economy and led her to challenge “the claim that litigation is a burden on the U.S. economy that prevents its efficient operation.”²⁰ Clark’s study of regions within six countries (Chile, Columbia, Costa Rica, Italy, Peru, Spain) found that “there is a positive relationship between elevated socioeconomic development and higher rates of civil litigation.”²¹ Ginsburg and Hoetker found that greater economic activity was marginally significantly associated with increased filings per capita in Japan.²² There may be limits to the positive relation in that it may be strong in relatively early stages of economic development and later level off. Data from England has been offered to support this hypothesis,²³ though within-country differences in economic development in Spain were associated with varying litigation rates.²⁴

Professor Galanter has noted that assertions of excessive litigiousness have some troubling roots in anti-Semitism.²⁵ But even the stereotype that Jews are more likely to be plaintiffs can simply be seen to reflect the association between economic well-being and litigation. In 2000, Galanter noted that a finding that Jewish residents of the Detroit metropolitan area in 1967 were more likely than others to go to lawyers was explained by researcher Matthew Silverman on economic grounds. “Silverman attributed greater Jewish involvement with the legal system to greater wealth and social integration than to religious or ethnic reasons.”²⁶ Economic prosperity was offered as a rational alternative explanation to not-so-thinly veiled bigotry.

Litigation rates of course are not merely a function of economic activity. Different dispute resolution institutions can lead two economically similar countries to have quite

Rev.* 647, 649 (2000) (“When faking [of claims] flourished in the early years of the Twentieth Century, it was often associated in the public mind with Jews.”, citing Ken Dornstein, *Accidentally on Purpose: The Making of a Personal Injury Underworld in America* 60 (1996)) (footnote omitted).

²⁶ Galanter, *supra* note 25, at 653 n.20 (2000).

different litigation rates.²⁷ Indeed, Clark found that within-country comparisons were much more appropriate in studying varying litigation rates than cross-country comparisons.²⁸ Within a country, Ginsburg and Hoetker showed that institutional changes in Japan—expansion of the bar, procedural reform, and the number of judges—were associated with litigation rates across prefectures.²⁹ Jacobi reported evidence that political factors, such as the division of state power between political parties, are associated with increased litigation rates.³⁰ We, therefore, include in our analysis of litigation rates important noneconomic factors for which information is available—noneconomic measures of well-being, urbanization, and litigation delay.

Our study complements two prior studies of India litigation. Guruswamy and Singh reported information about India's state-level litigation rates and state-level measures of well-being.³¹ They studied states' case filings for one year, July 1, 2008 to June 30, 2009, and informally compared them with state-level poverty rates, literacy rates, and violence.³² They observed a positive association between lower poverty rates, as measured in 2004-2005, and civil case filing rates in 2008-2009.³³ They also observed a positive association between higher literacy rates, as reported in the 2001 Census, and civil filing rates,³⁴ and a similar association between Naxalite violence³⁵ reported in 2008 and civil filing rates.³⁶ Hazra and Micevska studied state-level court congestion from 1995-1999 by assessing, *inter alia*, civil caseloads per capita and civil caseloads per judge.³⁷ They found a negative association between these caseload measures and state GDP per capita.³⁸ They attributed the negative association to states with greater resources being able to have a higher rate of clearing cases.³⁹

We extend Guruswamy and Singh's findings by focusing on additional factors affecting litigation, by analyzing more years of data, and by using statistical methods to test

³⁵ Naxalite is briefly described as follows:

Today, the peasant uprising that brought the word "Naxalite" to the lips of common people is forty years old. Naxalbari, where this peasant insurrection was born and subsequently entered into the national consciousness, is still a sleepy, quiet town in north Bengal. Although the revolution is over, and policemen are still killed either by bomb blasts or mines, and government officials are kidnapped for heavy ransom.

³⁹ *Id.*

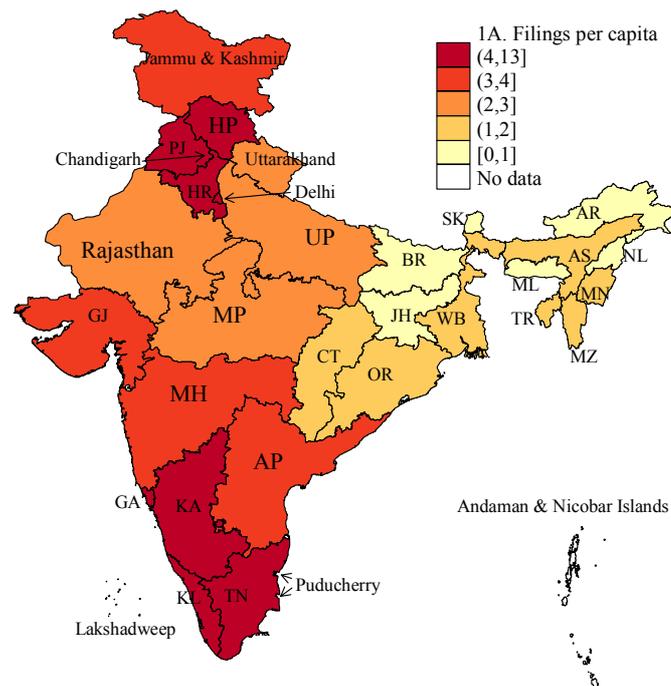

the likelihood of the observed relations occurring by chance. Our study differs from Hazra and Micevska's work because the litigation rates we study focus on new filings whereas their caseload measures included pending cases. Additional resources, as measured by GDP, may help process existing cases but need not similarly affect new case filing rates.

Part II of this article briefly describes India's legal system. Part III describes our hypotheses and the data we analyze. Part IV presents results on the relation between economic and other measures of well-being and litigation rates. Part V discusses the results and concludes.

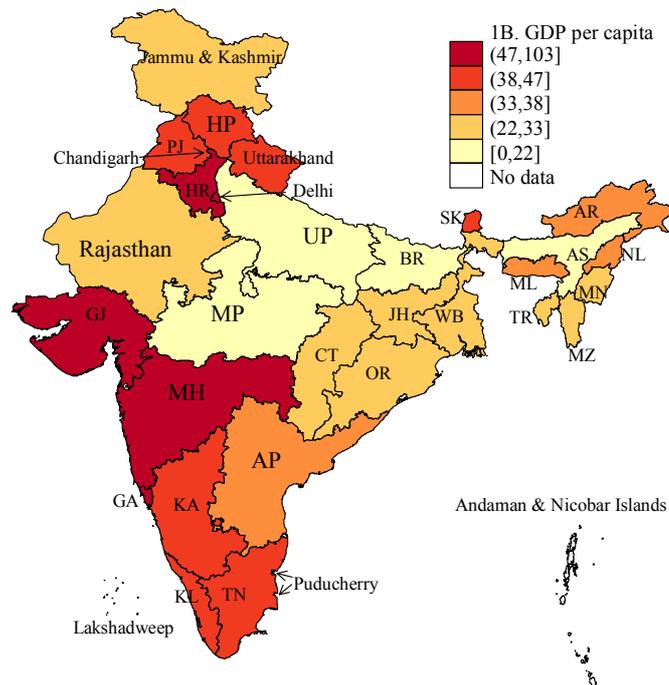

II. Background of India's Legal System

India consists of 28 states and seven union territories.⁴⁰ For ease of description we often refer to states and territories collectively as states. Figure 1 shows the states and territories; the color coding provides a summary of the civil filing and GDP data presented in more detail in Part IV.

Figure 1. Civil Filings and GDP Per Capita, by States, 2005-2010

⁴⁰ The territories are federally administered entities with distinctive legal features that may relate to assessing civil filings.

Note. Filings are civil filings per 1,000 persons using lower court filings averaged from 2005 to 2010. GDP is in thousands of rupees per capita averaged for that period. Filing data, GDP data, and state abbreviations are shown in Table 2 below. Union territories of Daman and Diu, Dadra & Nagar Haveli, and additional small Puducherry enclaves are not shown. Data not available for Andaman & Nicobar Islands and Lakshadweep.

India’s unified national court system is headed by the Supreme Court, High Courts of states below it, and lower courts below them. The High Courts have supervisory power over all courts in their jurisdiction.⁴¹ The judiciary is regarded as independent of the executive and legislature. Although the President of India appoints Supreme Court justices⁴² and High Court justices,⁴³ senior Supreme Court justices effectively nominate Court candidates and the President approves their nominees.⁴⁴ The lower courts include the most important courts of general jurisdiction, the district courts, of which there are about 600, and subordinate courts. As of December 31, 2010, there were 13,962 district and subordinate court judges.⁴⁵ Geographical jurisdiction for the 21 High Courts coincides with state and territory boundaries, with six High Courts having authority over more than one state or territory. Table 1 shows the allocation of states and territories to the High Courts.

Table 1. India High Courts Geographical Jurisdiction

Rajasthan	Rajasthan	
Sikkim	Sikkim	
Uttarakhand	Uttarakhand (formerly Uttaranchal)	

Note. The table shows the current allocation of states and territories to High Courts. During the periods covered by data we use, the Himachal Pradesh High Court was established in 1971, Sikkim became a state with its own High Court in 1975, the Gauhati High Court's jurisdiction was expanded to cover seven states in 1987, and Chhatisgarh, Jharkhand, and Uttarkhand all became states with their own respective High Courts in 2000.

III. Hypotheses and Data

India's federal structure allows testing hypothesized associations between litigation rates and both economic prosperity and other factors. For a within-country study of litigation rates and prosperity, India has the useful but lamentable characteristic of substantial variation in economic development. GDP per capita varies across states by nearly a factor of ten⁴⁶ compared, for example, to a variation by a factor of about two in the U.S.⁴⁷ We exploit this variation and similar state level variations in other attributes, such as education and life expectancy, to formulate and test hypotheses about their influences on litigation rates.

A. Hypotheses

As described above, scholars have long noted that economic growth may create more litigation.⁴⁸ More specifically, as economies grow in size and complexity, litigation increases, "both to resolve social conflict and more simply as a mechanism of economic

⁴⁶ Table 2 *infra*.

⁴⁷ U.S. state GDP calculations are based on the 2009 state population table and the 2008 state GDP table, available at U.S. Census Bureau, The 2012 Statistical Abstract: The National Data Book, available at <http://www.census.gov/compendia/statab/rankings.html>. Including the District of Columbia increases the variation to a factor of about five.

⁴⁸ F. Van Loon & E. Langerwerk, Socioeconomic Development and the Evolution of Litigation Rates of Civil Courts in Belgium, 1835-1960, 24 *Law and Society Rev.* 283, 285 (1990)

interaction.”⁴⁹ Like many studies,⁵⁰ we therefore hypothesize that litigation rates will be higher in Indian states that are more economically prosperous, based on state level measures of GDP per capita.

It is less widely acknowledged that noneconomic well-being may also be associated with litigation rates. An impoverished, uneducated field worker in poor health faces obstacles other than money to securing rights. Lack of education likely reduces knowledge of one’s private and public rights, ill-health may disable one from many activities, including litigation, and shorter life expectancies provide less time to sue. In addition to these direct effects on litigation, less education and shorter life expectancies may compromise economic development, and thereby indirectly influence litigation rates through economic measures.

In countries with substantially homogenous literacy and health rates, the influence of noneconomic well-being on within-country litigation rates may be difficult to detect and has not been analyzed. India’s states, much more than Japanese prefectures studied by Ginsburg and Hoetker, or U.S. states studied by Jacobi, substantially vary in noneconomic measures of human well-being, such as life expectancy, education, and literacy.⁵¹ In analyzing litigation rates, we employ a widely used measure of well-being that includes noneconomic factors, the Human Development Index. The HDI is a multidimensional measure of well-being that combines measures of life expectancy, educational achievement, and per capita expenditure.⁵² We speculate that litigation rates are positively associated with higher HDI scores.

India’s population density varies substantially across states.⁵³ Increased urbanization likely leads to greater business and personal interactions, thereby creating more opportunities for disputes and litigation. Interpersonal and kinship relations in urban settings may be generally weaker, thereby also contributing to litigation rates.⁵⁴ Lawyers tend to be more concentrated in urban areas, thereby reducing the transaction costs of obtaining a lawyer and thus promoting litigation.⁵⁵ Wollschläger’s study of litigation rates over time in Bremen notes that the effects of urbanization on litigation need “no comment”⁵⁶ and Ginsburg and Hoetker accounted for large urban prefectures in assessing filings.⁵⁷ Drawing similar inferences we also speculate that states with more urbanization will have higher litigation rates.

⁴⁹ Jacobi, *supra* note 20, at 214.

⁵⁰ E.g., Ginsburg & Hoetker, *supra* note 22; Jacobi, *supra* note 20.

⁵¹ Table 2 *infra*.

⁵² E.g., United Nations Development Programme (1999). *Human Development Report 1999*. New York: Oxford University Press; <http://hdr.undp.org/en/statistics/>. The HDI index measures health (life expectancy), living standards (GDP per capita), and education (measured by years of schooling). Jeni Klugman, Francisco Rodriguez & Hyung-Jin Choi, *The HDI 2010 : New Controversies, Old Critiques*, United Nations Development Programme, Human Development Reports, Human Development Research Paper 2011/01, at 3 (April 2011). In 2010, gross national income replaced GDP as the measure for living standards. *Id.* at 15.

⁵³ Table 2 *infra*.

⁵⁵ *Id.* at 38-39.

⁵⁶ Wollschläger, *supra* note 6, at 279 (“The specific effects of urbanization . . . on litigation need no detailed comments here.”).

⁵⁷ Ginsburg & Hoetker, *supra* note 22, at 49.

Accounting for institutional features of a legal system is important in assessing litigation rates, as shown, for example, in Ginsburg and Hoetker's Japan study.⁵⁸ The two most notable institutional features of India's judiciary are perhaps a widespread belief in the existence of substantial corruption⁵⁹ and delays due to a large backlog of cases. India's lower court case backlog was over 26 million cases as of 2008.⁶⁰ We lack information to study the effect of corruption, but have reasonable information about filed, pending, and disposed cases to account for the degree of delay across states. Evidence exists that the expected time to adjudicate as between judge and jury trial influences the choice of trial mode in a U.S. context with less dramatic delay than India's.⁶¹ We expect greater delay to discourage litigation and to be associated with reduced litigation rates.

B. Data

Data on Litigation Rates. To assess litigation rates, we use two types of civil filings: one based on filings in the district and subordinate courts (collectively, the lower courts) and a second based on filings in the High Courts. The case filing data are for civil cases filed in each state's lower courts, as reported in the India Supreme Court's *Court News*, which is published four times per year and contains quarterly data for the years 2005 to 2010.⁶² *Court News* also provided High Court civil filing data comparable to the lower court data. For High Courts not coterminous with a single state, we recalculated total population at the High Court level, using the geographical coverage of the High Courts shown in Table 1 to compute filings per capita. Data on lower court filings are also available for 1977 from a report of the Law Commission of India.⁶³ We have not located conveniently available lower court civil case filing data for years before 2005, other than for 1977.

Lower court data have the advantage of including the mass of civil filings and so likely provide the most thorough measure of litigation activity. High Courts are more removed from the mass of civil filings and their appellate dockets exclude all the cases that never lead to appeals. Parties may forego appealing for reasons that apply in any country, including acceptance of the lower court's ruling as correct or, even if the ruling is believed to be incorrect, an estimate that the chance of success on appeal is too low to warrant the

⁵⁸ Id. at 37-42 (accounting for expansion of the bar, law reform, and system capacity as measured by the number of judges).

⁵⁹ E.g., Centre on Law and Jurisprudence, *supra* note 7, at 45 (judicial salary increase needed to promote a corruption free judiciary).

⁶⁰ Id. at 9 (26.4 million cases were pending in the lower courts as of 2008); Kannan Kasturi, *Civil Litigation? No, thanks, India Together* (July 12, 2009) (30 million total case backlog), available at <http://www.indiatogether.org/2009/jul/gov-civil.htm>.

⁶¹ Kevin M. Clermont & Theodore Eisenberg, 77 *Cornell L. Rev.* 1124, 1147-48 (1992) (showing that litigants tend to select shorter trial queue in opting for judge versus jury trial).

⁶² Much of the filing data are also available at <http://www.indiastat.com>, which requires password or IP access. Prior to 2005, the available data do not provide separate numbers for civil cases instituted in a year. E.g., Ministry of Law and Justice, Govt. of India, *State-wise Number of Civil and Criminal Pendency Cases in District/Sub-ordinate Courts in India* (As on 30.06.2004).

⁶³ Law Comm'n of India, *Seventy Seventh Report: Delay and Arrears in Trial Courts* (Nov. 1978).

investment. In the U.S., for example, the vast majority of trial court outcomes are not appealed.⁶⁴

High Court data, however, have some advantages. First, only 21 High Courts exist and they presumably have reasonable information about their own case filings. Lower court data used for this study were supplied to the High Courts from hundreds of lower courts, which then supplied them to the Supreme Court. This process provides less assurance of consistent reporting for lower courts. Second, High Court filings provide a measure of what, on average, are likely the most important cases. They are the cases that parties press to appeal and presumably tend to involve higher stakes. A High Court, for example, had original jurisdiction over the case against then-Prime Minister Indira Gandhi⁶⁵ that led to the declaration of the state of Emergency from June 26, 1975 to March 23, 1977, during which opposition political party leaders were arrested, press censorship was used, and elections were postponed. Third, High Courts in India have much wider original jurisdiction than in many other countries, including jurisdiction over revenue matters⁶⁶ and jurisdiction to issue writs of habeas corpus, mandamus, prohibition, quo warranto, and certiorari.⁶⁷ Original jurisdiction High Court cases can number in the tens of thousands in a year⁶⁸ and reached 52 percent of cases filed in the state of Orissa in 2009.⁶⁹ So many High Court cases exist that did not begin in the district and subordinate courts. Fourth, High Court data provide a check on the lower court data. A high association between lower court and High Court filings ought to exist across the states. An appeal cannot be filed without a lower court ruling so lower court activity imposes a fundamental constraint on High Court activity that should promote an association. And concerns about India's civil justice system have generated the view that High Courts are extremely reluctant to deny admission of appeals.⁷⁰

Separate recent lower court civil case filing data are available for the 28 states and for the three largest union territories: Delhi, Chandigarh, and Puducherry. India has four other union territories, all substantially smaller, with an aggregate population of about one million

⁶⁵ *State of Uttar Pradesh v. Raj Narain* (Allahabad High Court). The Supreme Court of India stayed the ruling and later overturned the conviction of Gandhi. A.I.R. 1975 S.C. 865.

⁶⁶ India Const. art. 225. It is reported that six High Courts have original jurisdiction in civil cases involving sufficient amounts and other High Courts have more specialized original jurisdiction, Arnub Kumar Hazra & Bibek Debroy, *Introduction: Issues and Aspects of Judicial Reforms*, in Hazra & Debroy eds., *supra* note 37, at 15, 17-18.

⁶⁷ India Const. art. 226(1).

⁶⁸ Department of Economics and Statistics, Govt. of Tamil Nadu, *Number of Disposal and Pendency of Civil Cases in High Court and Subordinate Courts (Civil) in Tamil Nadu (01.01.2008 to 31.12.2008)* (showing 14,920 High Court Original Side cases commenced); *Statistical Abstract of Andhra Pradesh 2001*, Govt. of Andhra Pradesh, *Number of Disposals and Pendencies of Petitions in High Court of Andhra Pradesh (2000-01)* (showing 121,277 original suits).

⁶⁹ This is based on analysis of the Supreme Court's *Court News* publications that contain data for 2009. The nationwide percentage of cases filed in High Courts for that year was 22 percent.

⁷⁰ Pratap Bhanu Mehta, *India's Judiciary: The Promise of Uncertainty*, in *Public Institutions in India: Performance and Design* 181 (Devesh Kapur and Pratap Bhan Mehta eds. 2005).

people,⁷¹ less than 0.1 percent of India's 1.2 billion population. These small union territories are not included in our lower court analysis.⁷²

Our analysis of lower court and High Court filing data covering 2005 to 2010, reported below, established that High Court data are a reasonable proxy to assess the relation between economic prosperity and civil filings. We therefore extended our analysis to years for which High Court filing data were available prior to 2005. High Court civil filing data for the years 1964 to 1983 (other than 1966) are contained in the Jaswant Singh Commission Report,⁷³ a government study undertaken to assess adding High Courts or benches (locations) within High Courts. To compute High Court per capita civil filings and GDP per capita for the earlier time period, we used the 1961 Census data for the years 1964 to 1965, for the years 1967 to 1976 we use the 1971 Census data, and for the years 1977 to 1981, we use the 1981 Census data.

Data on Economic Well-Being. As a measure of economic well-being for the time period 2005 to 2010, we used state level data for each year provided by the Ministry of Statistics and Programme Information, Government of India. The data are reported as net state domestic product in rupees at current prices,⁷⁴ which is gross domestic product minus depreciation on capital goods.⁷⁵ Some suggest that net domestic product is a better measure of growth than GDP,⁷⁶ and data for it are the best conveniently available data on economic growth that we have located at the state level. We take the liberty of referring to it as GDP because that term is so commonly associated with measures of growth.⁷⁷ For High Courts not coterminous with single states, we recalculated total GDP at the High Court level, using

⁷¹ The four smaller union territories are Andaman and Nicobar Islands, Dadra and Nagar Havel, Daman and Diu, and Lakshadweep.

⁷² Delhi is India's National Capital Territory, India Const. art. 239AA(1), has the largest metropolitan area in India, and the second largest metropolitan population, and is one of the ten largest metropolitan areas in the world. Its administration includes its own legislature, High Court, and executive council of ministers headed by a chief minister. India Const. art. 239AA. Chandigarh is a union territory and planned city that arose out of the partition of British India into Pakistan and India. Lahore, the capital of the former province of Punjab became part of Pakistan, but part of the Punjab also became part of India. That geographical entity needed a new capital. In addition, in 1966, the new state of Haryana was created out of the eastern portion of India's Punjab. The surviving portion of Punjab had a Sikh and Punjabi language majority. Haryana had a Hindu and Hindi language majority. Chandigarh serves as the capital of two states, Punjab and Haryana, and is, by Indian standards, of modest size with a population of about one million. Puducherry is a union territory that was a French colony consisting of four districts that are not contiguous. Like Delhi, Puducherry has its own elected legislative assembly and executive council of ministers. India Const. art. 239A. Puducherry's population is larger than Chandigarh's but is less than 1.5 million people.

⁷⁴ Press Information Bureau, Govt. of India, Ministry of Statistics and Programme Implementation, Per Capita Net State Domestic Product at Current Prices (Aug. 4, 2011) (Release Id :73929), available at <http://pib.nic.in/newsite/AdvSearch.aspx> (search term "per capita income" (without quotation marks)), accessed 3/19/2012.

⁷⁵ These net domestic product data come from the Central Statistical Organization, Govt. of India.

⁷⁶ Roland Spant, Why Net Domestic Product Should Replace Gross Domestic Product as a Measure of Economic Growth, Number Seven 39 (Fall 2003), available at <http://www.csls.ca/ipm/7/spant-e.pdf>. This source also compares net domestic product and GDP performance for OECD countries, showing generally little difference. Id at 42.

⁷⁷ For India, these data have sometimes erroneously been referred to as GDP data. List of Indian States by GDP, http://en.wikipedia.org/wiki/List_of_Indian_states_by_GDP.

the geographical coverage of the High Courts shown in Table 1. As a measure of economic well-being for the High Court data for the period 1964 to 1983, we again used GDP at the state level.

Data on Noneconomic Well-Being. As noted above, we used the HDI as a measure of noneconomic well-being. We have state-level data for fewer geographical units for the HDI than for litigation rates and GDP. So analyses below that include the HDI encompass fewer states but still include a substantial majority of the states. The state-level HDI data used here are for 2007-2008, come from the India Human Development Report published in 2011, and are reported as of this writing to be the most recently available state-level HDI measure.⁷⁸ We also explore the association between litigation rates and literacy rates. We have used literacy rates from the 2011 Census.

Data on Urbanization. We used population density as a measure of urbanization. Density is computed by dividing a state's population in the 2011 Census by its square kilometers to yield the number of inhabitants per square kilometer. The decennial census data from the Ministry of Statistics and Programme Implementation provided population density information.⁷⁹

Data on Court Backlogs. Our analysis of the relation between litigation rates and court backlogs is limited to 2005 to 2010 and to the lower courts, where most cases begin. Data on filing, pending, and disposed cases come from *Court News*. As a measure of the backlog, for each state for each year, we divided the number of pending civil cases by the number of disposed civil cases. This yielded the number of years needed to clear the civil docket, as shown in Table 2. The number of years required to clear the civil docket should not be confused with the average number of years required for a case to be heard and decided by a court. Many cases are settled or withdrawn before they are heard, but these cases are still counted as disposals. This measure of backlog also effectively assumes a first-in/first-out treatment of cases, with subsequently filed cases being delayed until previously filed cases are processed. Since some classes of litigation enjoy priority⁸⁰ and other factors undoubtedly are at work, the measure is not intended as a precise indicator of how long cases will remain on the docket or how many years it would take for a case to be decided by a court. We merely use it as a proxy for comparing delay across states. Note that the measure effectively accounts for other factors that may influence case processing time, such as the number of judges in a state's court system and the economic resources devoted to the court system. The effect of more judges or resources should translate into greater capacity to process cases and therefore be accounted for by the time needed to clear the cases from the system.

Data Limitations. Two primary challenges exist in using data available on the Indian court system. The first is the potential for lack of uniformity in record keeping over time and across states. In data available for 1977, for example, regular hearing and miscellaneous filings are disaggregated. (Examples of miscellaneous filings are interlocutory appeals,

⁷⁸ Institute of Applied Manpower Research, Planning Comm'n, Govt. of India, India Human Development Report 2011, at 24 (tbl. 2.4).

⁷⁹ http://mospi.nic.in/Mospi_New/site/India_Statistics.aspx?status=1&menu_id=14, Table 2.1, accessed 2/12/2012.

⁸⁰ Law Comm'n of India, *supra* note 63, at 37 (listing matrimonial, eviction, Motor Accident Claims Tribunal, and India Succession Act cases as in need of priority).

requests for stay, and requests for interim orders. These filings result out of preexisting regular hearing filings.) The data for 2005-2010 seem to only include regular hearing filings, but the inclusion of miscellaneous filings by any of the state courts would create inconsistencies in the data.⁸¹ A state-specific concern is that Tamil Nadu's filing rate, as shown in Table 2 below, is far above that of any other state and exceeded only by the much more densely populated and far more prosperous union territory of Puducherry. It would not be surprising if Tamil Nadu courts account for cases differently than other states.⁸²

Second, is the potential for error in record keeping. Most data available for different state lower and high courts seem to vary reasonably from year to year. However, there are occasionally unexplained spikes or dips in litigation filing, some of which we refer to in reporting results.⁸³ This may represent actual volatility in litigation filing or may simply be a record keeping error. Overall, the data on the Indian courts is reasonably uniform, meaning that although these potential challenges should be kept in mind they do not seem to significantly undercut our conclusions.

Our analysis has limitations other than the consistency and accuracy of the data. The lack of data at the district level is a concern. Although many state level empirical and policy studies in India and the U.S. exist, state level comparisons cannot account for within state heterogeneity. State level studies effectively treat New York City the same as upstate New York and Mumbai the same as rural Maharashtra. India's substantial differences between urban and rural areas, even within states, suggests that state level studies necessarily oversimplify. The sheer size of some Indian states exacerbates this concern. Uttar Pradesh's population of approximately 200 million people, standing alone, would make it the fourth most populous country in the world. Representing its economy and courts using statistics for the entire state is not fully satisfactory. The available data also do not include useful information about subcategories of civil cases. Some hypothesized relations, such as the effect of the HDI on filings, likely influence different types of cases to different degrees. Finally, data on civil filing rates is not available for different income and social groups. For example, although India's litigation rate overall may be low compared to a country like the U.S.,⁸⁴ the filing rate of Indians making over \$30,000 a year may be as high or higher than Americans in a comparable income bracket. To more accurately compare whether a society

⁸¹ We used the comparable filings data available for 1977.

⁸² Some possible sources of variation do not appear to be a concern. The volume of family court cases was not large enough to materially affect results. Lok Sabha (the lower house of the Indian Parliament) Unstarred Question No. 6743, dated on 06.05.2010, Selected State-wise Number of Cases Instituted, Disposed and Pending by Family Courts in India (2007 to 2009) (showing less than 250,000 new family court cases per year). Nor does the number of cases disposed of by Lok Adalat (people's court) methods seem large enough to affect the observed patterns. National Consumer Disputes Redressal Comm'n, State-wise Number of Cases Disposed off [sic] by Lok Adalat Methods in India (As on 05.08.2011); Lok Sabha Unstarred Question No. 3571, dated. 20.08.2004, Number of Lok Adalats held and Cases Disposed off [sic] in Tamil Nadu (2001-2002 to, 2003-2004). For a discussion of Lok Adalats, see Galanter & Krishnan, *supra* note 10.

⁸³ See note 89 *infra* and text accompanying Figures 9 to 12 *infra*.

⁸⁴ Jacobi shows mean filings of 168,764 and mean population of 5,034,887 for U.S. states. Jacobi, *supra* note 20, at 208 (tbl. 1). This corresponds to filings of 33.5 per 1,000 persons, far higher than the per capita filing rate for any Indian state shown in Table 2 *supra*.

is more litigious than another one would prefer to contrast the filing rates of like social groups, whether measured by GDP per capita, HDI, or other relevant factors.⁸⁵

Table 2 provides summary statistics for our key variables for the 31 geographical units we analyze using lower court filings.⁸⁶ The state abbreviations in Table 2's second column are used in the figures. To compute 2005 filings per capita, we divided the annual court filings by the state's 2001 population, which is reported in the India 2001 Census⁸⁷ and contains the census information closest in time to 2001. For the 2006 to 2010 filings per capita, we divided the annual court filings by the state's 2011 population, as reported in the India 2011 Census,⁸⁸ which contains the census information closest in time for 2007 to 2011, and equally close to 2006 as is the 2001 census data. The states' civil filings shown in the table are average filings from 2005 to 2010. The GDP per capita and case backlog data in the table are similarly averaged. The filing and GDP data are shown graphically in Figure 1 above. GDP amounts are in rupees and, as of this writing, the exchange rate for rupees is 50.405 per dollar. As stated above, the backlog data show the years needed to clear a state's civil case backlog based on the number of civil cases pending and disposed in a year.⁸⁹

⁸⁵ Ideally, one would also like a more precise measure of possible litigation events than proxies such as population or economic conditions. For example, a study of tort litigation in Thailand used motor vehicle registrations as a proxy for possible automobile accident litigation. David M. Engel & Jaruwat S. Engel, *Tort, Custom, and Karma: Globalization and Legal Consciousness in Thailand* 106 (Stanford University Press 2010).

⁸⁶ We aggregated the case filing data across the relevant *Court News* issues (four per year) for each calendar year to compute each state's case filings for the years studied.

⁸⁷ Registrar General & Census Commissioner of India, *Census of India 2011, Provisional Population Tables, Paper 1, Series 1, Chapter 3, Size, Growth Rate and Distribution of Population*, p. 47, available at http://www.censusindia.gov.in/2011-prov-results/data_files/india/Final%20PPT%202011_chapter3.pdf.

⁸⁸ *Id.*

⁸⁹ The backlog average for Mizoram is questionable because the 2005 data show only 23 cases disposed and 834 cases pending, leading to a Years to clear backlog for that year of 36.3 years. Excluding 2005 leads to a Years to clear backlog of 1.7 years.

Table 2. India States' Civil Filings & GDP, 2005-2010, HDI, Literacy, Population, Population Density, Backlog

	State abbreviation	Filings per 1000 persons	GDP per capita (rupees)	HDI	Literacy Rate 2011 (%)	Population 2011 (millions)	Population 2001 (millions)	Population per sq. kilometer	Years to clear backlog

West Bengal	WB	1.5	30,582	0.492	77.1	91.3	80.2	1029	4.3

Note. n/a=not available; HDI=Human Development Index. Filings per 1000 persons, GDP per capita, and Years to clear backlog are six year averages unless data were unavailable for a state-year observation. Population is based on the 2001 and 2011 Censuses; population density and literacy are based on the 2011 Census. GDP is in rupees per annum. HDI is for 2007-08. Case filings for Goa were not reported in *Court News* until 2007. Data for filings or GDP are missing for: Goa 2005, 2006; Nagaland 2010; Tamil Nadu 2009; West Bengal 2007. Sources. India Sup. Ct. High Court News; Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India; India Human Development Report 2011. indicates geographical unit is a union territory.

The table shows that India's states substantially vary in both civil litigation activity and in our measures of well-being, GDP per capita, the HDI, and literacy rates. The states varied in filings per 1,000 persons in a year from 0.4 in Arunachal Pradesh to 14.1 in Puducherry. State GDP per capita figures varied from 11,600 in Bihar to 102,500 in Goa. The HDI varied from 0.790 in Kerala to 0.358 in Chhatisgarh.⁹⁰ States also varied substantially in population and in population density. Population density ranged from 17 per square kilometer in Arunachal Pradesh to 11,297 per square kilometer in Delhi. In states with substantial populations, the years needed to clear the civil case backlog varied from 0.7 years in Tamil Nadu to 5.8 years in Bihar.

IV. Results

We first report bivariate results describing the relation between litigation rates and explanatory factors. We then report multivariate regression models that assess the combined influence of the factors on litigation rates.

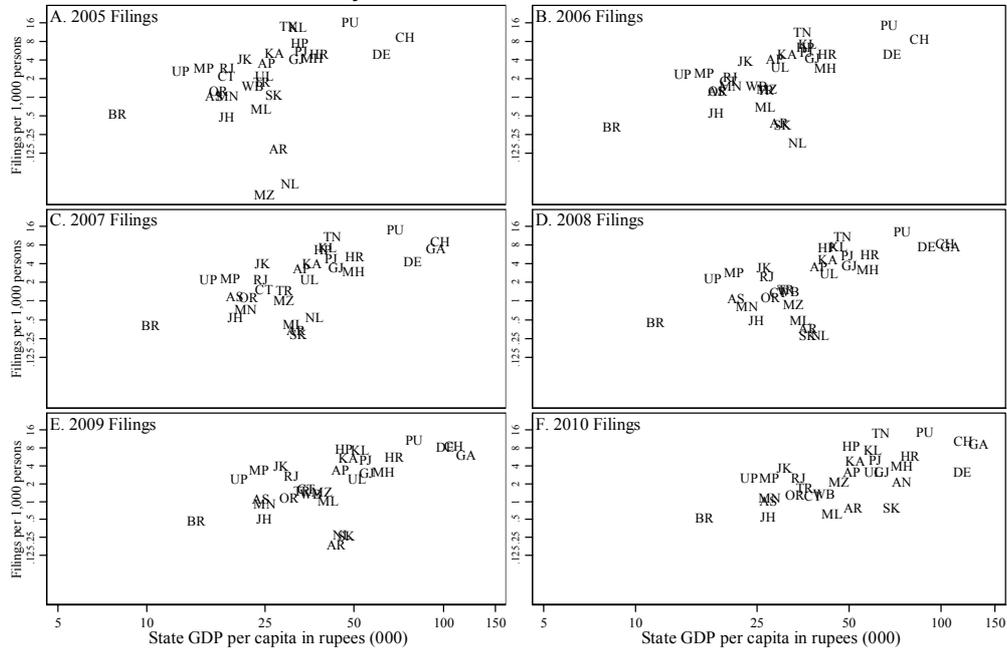

A. Bivariate Results

1. Litigation Rates in Lower Courts: Economic Prosperity and Urbanization

Figure 2 shows the relation, for each Indian state or major territory, between civil case filings per capita, on the y-axis, and GDP per capita, on the x-axis. Each of the six subfigures shows the relation for one year, beginning with 2005 in the upper left subfigure, followed by 2006 in the upper right subfigure, and ending with 2010 in the lower right subfigure. The data points in the subfigures are labeled with state abbreviations to show which Indian state has the indicated civil filings and GDP. For example, the state of Bihar (BR) had the lowest GDP per capita in each year and also had relatively low civil case filings per capita in each year.

⁹⁰ India as a country ranked 119th in the world in the 2010 HDI rankings, with a national HDI of 0.512, which is equivalent to the South Asian average HDI. Institute of Applied Manpower Research, *supra* note 78, at 17.

Figure 2. India Civil Filings Per Capita and GDP Per Capita, by State, Trial Level 2005-10

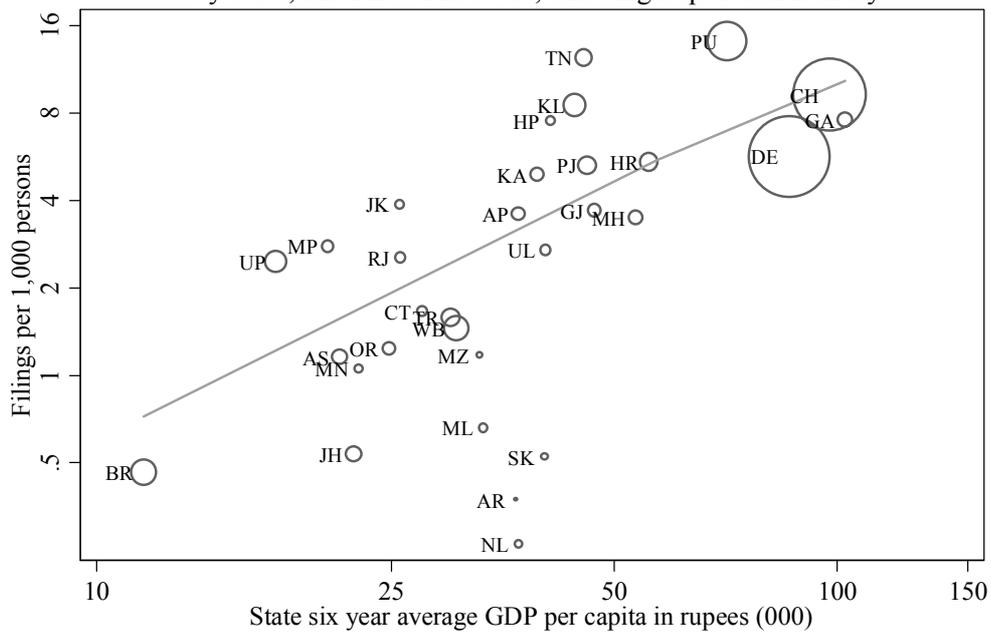

Note. GDP data are based on fiscal years beginning April 1 and ending March 31. State abbreviations are in Table 2. x and y axis scales are in logs. Sources. India Sup. Ct. High Court News; 2001 and 2011 Censuses; Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India.

The figure shows that the relation between civil filings and GDP per capita was reasonably stable over the six-year period. A pattern of higher filing rates being associated with higher GDP per capita persisted. The figure also shows that the territories of Delhi (DE), Chandigarh (CH), and Puducherry (PU) consistently had relatively high civil filings, accompanied by relatively high GDP. These territories are also distinctive in their population densities (our measure of urbanization), as shown in Table 2, which are by far the highest in India. Some low-population states, Arunachal Pradesh (AR), Meghalaya (ML), Mizoram (MZ), Nagaland (NL), and Sikkim (SK), showed the greatest departures from the pattern of increased civil filings being associated with increased GDP per capita.

Figure 3 shows the average civil filings per capita and GDP per capita for the six years for which we have data, but now adds population density information from Table 2. The density information helps illuminate the distinctive features of both the territories and the low-population states that emerge in Figure 2. The data points in Figure 3 for each state are indicated by hollow round circles, which are proportionate in size to a state's population density. The state abbreviations labeling the data points are located to the left of the data points. Delhi, Chandigarh, and Puducherry have by far the three highest population densities, had high GDP per capita, and had high case filing rates. So these large union territories are distinctive as legal entities, but also have high population densities, which may be associated with high civil litigation rates. The low-population states had low population densities and low

case filing rates, and non-distinctive GDP per capita levels. The straight line in Figure 3 shows the predicted values from a regression of the relation between filings and GDP. It confirms the positive association between the two variables. The correlation between filings and GDP is strong, with a correlation coefficient of 0.59 (using log transformations), which is significant at $p=0.0004$. If one excludes the small, outlier states (ML, SK, AR, and NL), the correlation coefficient is 0.76, significant at $p<0.0001$.

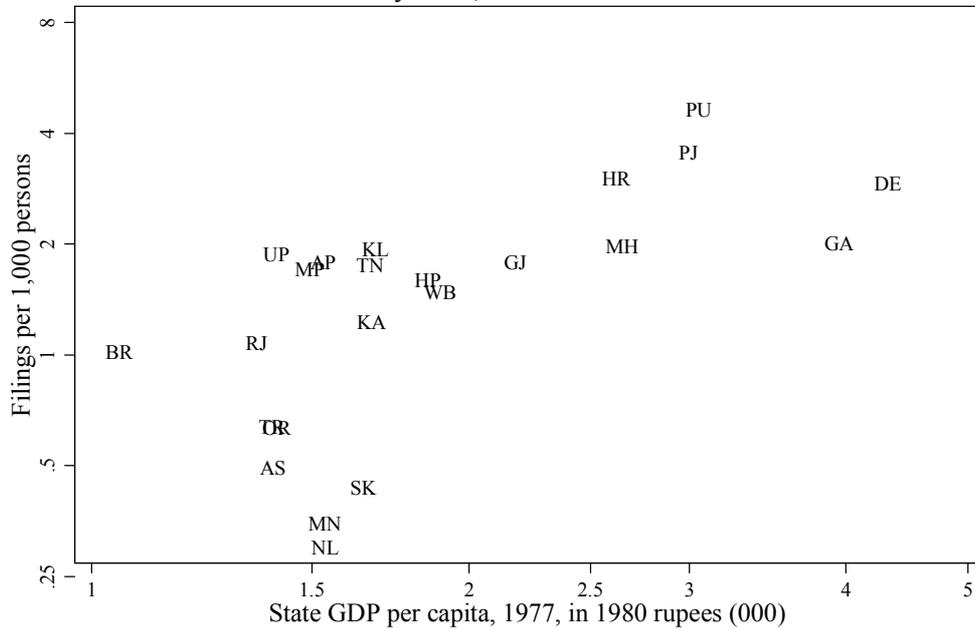

Figure 3. India Civil Filings Per Capita and GDP Per Capita, by State, Trial Level 2005-10, Showing Population Density

Note. The circles show the data points and the circle sizes are proportional to the states' population densities. State abbreviations are in Table 2 and appear to the left of the circles representing the state's data. x and y axis scales are in logs. Sources. India Sup. Ct. High Court News; 2001 and 2011 Censuses; Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India.

Figure 4 shifts the analysis from the 2005-2010 time period and shows the relation between 1977 lower court filings data and GDP per capita. The correlation between filings and GDP is similar to that in Figures 2 and 3, and again large and statistically significant (0.64; $p=0.001$).

Figure 4. India Civil Filings Per Capita and GDP Per Capita by State, Trial Level 1977

Note. State abbreviations are in Table 2. x and y axis scales are in logs. Sources. Law Comm'n of India, Seventy Seventh Report; 1981 Census, Directorates of Economics & Statistics of respective State Governments.⁹¹

We thus have evidence that the strong filings-GDP association at the lower court level dates back over 30 years and of a filings-urbanization association for recent years.⁹² This information allows for assessing within-state variation over time as reported below.

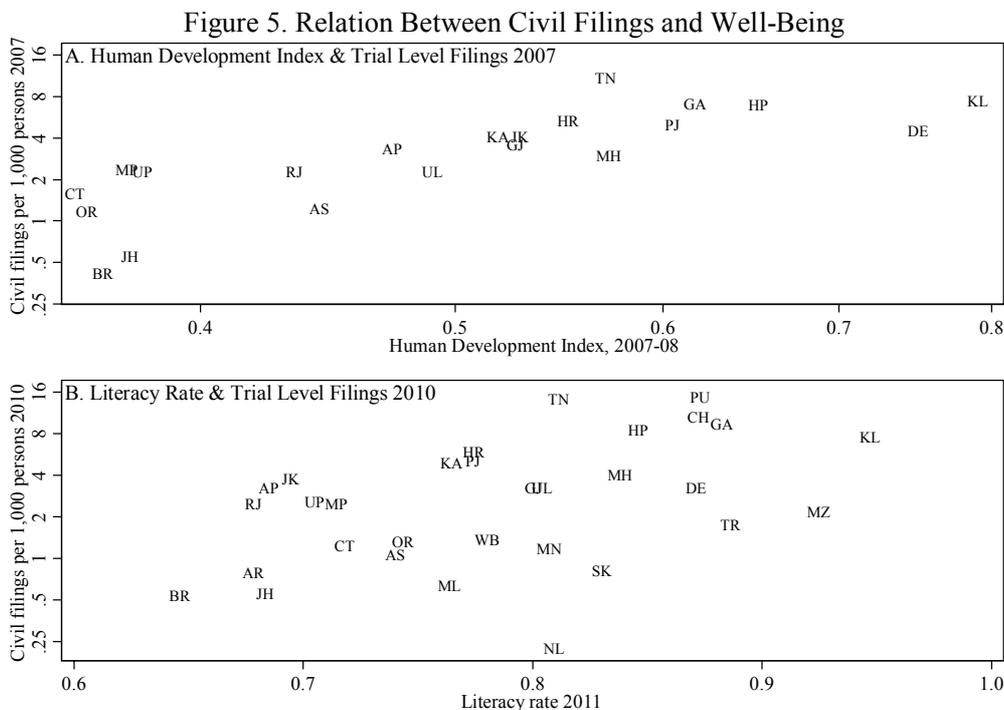

2. Litigation Rates in Lower Courts and Noneconomic Well-Being

As noted above, GDP measures capture only one aspect of a population's well-being that may affect litigation rates and India has large internal differences by other important measures of human well-being. Figure 5 compares two other measures, HDI and literacy rates, with civil case filings. We use case filings in the year closest to these available measures: 2007 for the HDI data and 2010 for the 2011 Census-based literacy rates. As in the case of GDP and as suggested by the figure, a strong, statistically significant correlation exists between HDI and filings and between literacy rates and filings. For the 21 states for which we have civil filings and HDI data, the correlation coefficient (after log transformations) is 0.80 ($p < 0.0001$). For those 21 states, the correlation between HDI and civil filings is larger than the correlation between GDP and civil filings (0.743; $p = 0.0001$). For those same 21 states, the correlation

⁹¹ The GDP data come from Ministry of Statistics and Programme Implementation, available online at http://mospi.nic.in/Mospi_New/upload/SDP_%201980_81_4june08.pdf.

⁹² GDP per capita and population density are also significantly positively correlated (correlation coefficient=0.34) but less strongly than is civil filings with each of GDP per capita and population density.

coefficient (after log transformation of filings only) for literacy rates is 0.70 ($p=0.0005$).⁹³ The patterns in the figure suggest a stronger association between HDI and filings than between literacy rates and filings. HDI's stronger association than GDP with filings will be explored further in the regression models below.

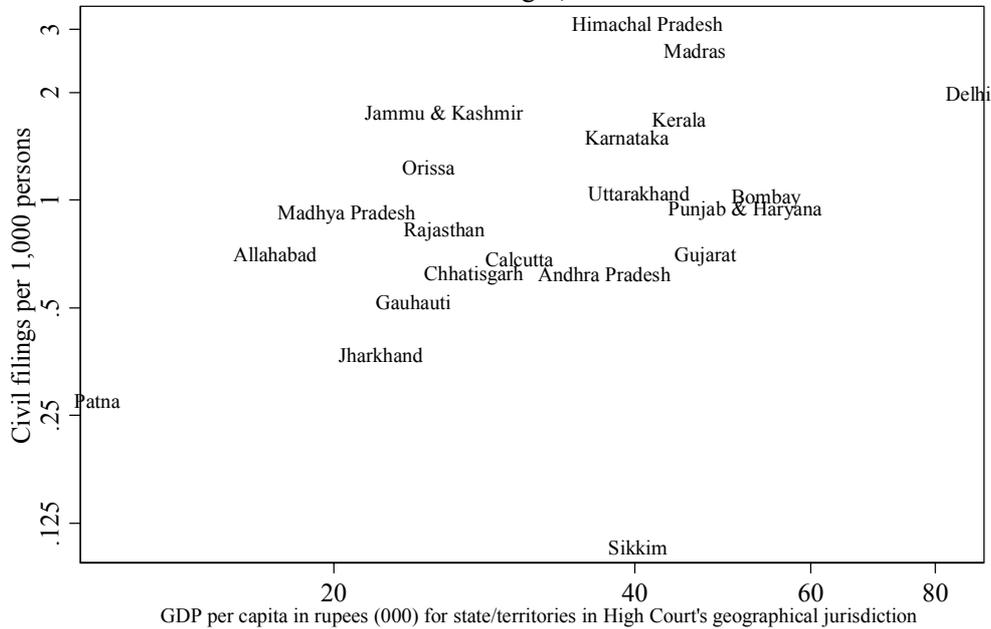

Note. State abbreviations are in Table 2. x and y axis scales are in logs. Sources. India Sup. Ct. High Court News; 2001 and 2011 Censuses; India Human Development Report 2011.

3. Litigation Rates in High Courts and Prosperity

As noted above, the High Court filings-GDP relation provides important potential confirmatory and supplementary information to the lower court filings-GDP correlation. We have analyzed the relation for each of the years 2005 to 2010 and summarize it in Figure 6 using the averages for the six-year period.

⁹³ Direct comparison of the correlations is of limited value because of the different scales and nature of the non-filing variables.

Figure 6. High Court Civil Filings Per Capita and GDP Per Capita Six Year Averages, 2005 to 2010

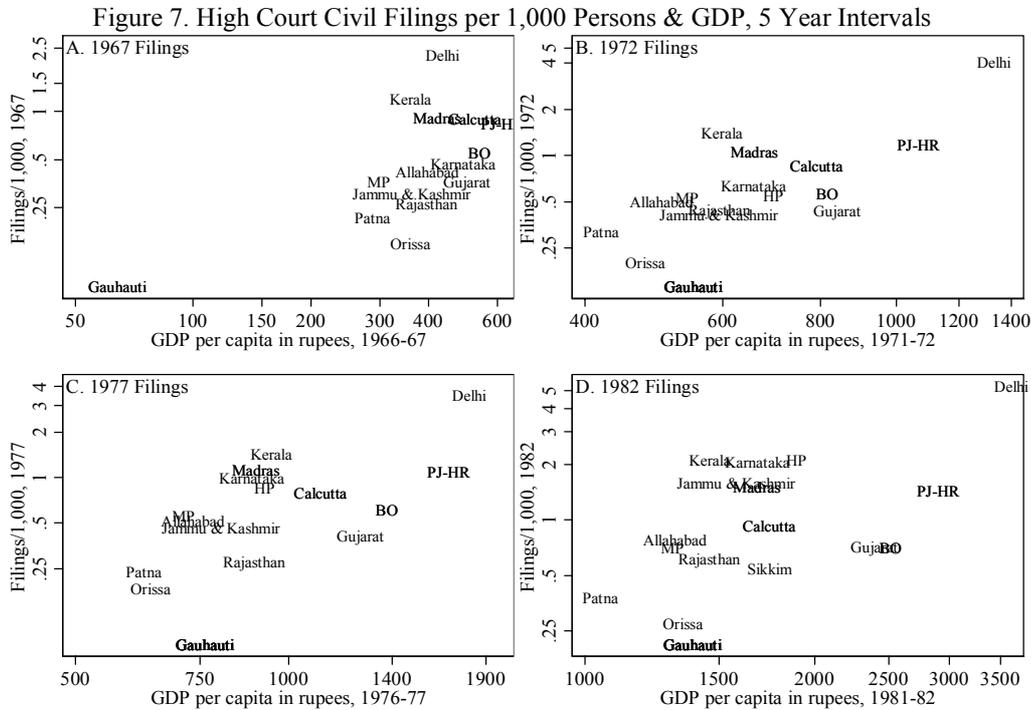

Note. x and y axis scales are in logs. Sources. India Sup. Ct. High Court News, 2001 and 2011 Censuses, Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India.

Figure 6 confirms a strong association between filings and per capita GDP. For each year and for the six-year averages, a strong and statistically significant filings-GDP association exists, though the strength of the relation depends on excluding Sikkim. The figure also suggests that the Sikkim High Court does not fit the overall pattern. That court, with jurisdiction limited to the state of Sikkim has, as shown in Table 2, a small population and services the fewest people, less than one million, of any High Court by a substantial margin. The strength of association between High Court filings and GDP is similar to the strengths of association between lower court filings and GDP, reported above, though direct comparison is limited due to different numbers of observations and different outliers. If one includes Sikkim, the correlation coefficient for High Court filings and GDP is 0.50, which is statistically significant at $p=0.0032$; the correlation coefficient increases to 0.65, significant at $p=0.0001$ if one excludes Sikkim.

More importantly, Figure 6, in conjunction with the lower court data, suggests that using High Court data to assess the filings-GDP relation yields results similar to those using the lower court data in Figures 1, 3, and 4. We exploit Figure 6's evidence that High Court data are useful proxies for the relation between the mass of filings and economic well-being by using the 1964 to 1983 High Court data to assess this connection over a longer period of time. To conserve space, Figure 7 reports the filings per capita-GDP relation for four years, spaced five years apart: 1967 (Figure 7A, upper left), 1972 (Figure 7B, upper right), 1977 (Figure 7C,

lower left), and 1982 (Figure 7D, lower right). The y-axes are filings per 1,000 persons and the x-axes are GDP per capita in current year rupees.

Note. BO=Bombay, HP=Himachal Pradesh, MP=Madhya Pradesh, PJ-HR=Punjab & Haryana. GDP amounts are based on fiscal years beginning April 1 and ending March 31. Himachal Pradesh High Court was established in 1971. Sikkim became a state in 1975. GDP data for Sikkim for 1976-77 were missing in the Central Statistical Organization (CSO) source. x and y axis scales are in logs. Sources. CSO; 1971 and 1981 Censuses; Jaswant Singh Comm'n Report.

The data confirm the pattern for the 2005 to 2010 data. A strong, statistically significant association between filings per capita and GDP per capita persists throughout the years. The pattern is less visible in Figure 7A because in 1967 the Delhi High Court's jurisdiction included the area that later became the State of Himachal Pradesh in 1971. The Delhi High Court area's relative leap in prosperity from 1967 to 1972 (shown by comparing the x-axes values for Delhi in Figures 7A and 7B) is likely due to the carving out of the relatively poorer Himachal Pradesh area as a state with its own High Court. Himachal Pradesh's ("HP" in Figures 7B, 7C, and 7D) lower prosperity can be seen in the 1972, 1977, and 1982 data. Thus, Delhi proper likely was the most prosperous High Court geographical area, even in 1967. This effect is confirmed by inspection of figures (not shown here) for the years prior to and after 1972. In each year for which we have data, Delhi's prosperity relative to other High Court areas is similar to that in 1967 for 1970 and earlier years, and similar to that in 1972 for 1973 and later years.⁹⁴ Carving out Himachal Pradesh was a milestone event in terms of the Delhi High Court area's relative prosperity.

⁹⁴ 1971, the year of the Himachal Pradesh High Court's creation, is a transitional year that we did not explore.

Gauhati is a persistently low-filing High Court in Figure 7. Gauhati has jurisdiction over India's seven northeastern states, all of which have small populations, as shown in Table 2, except for Assam. Yet Figure 6 shows that, in recent years, Gauhati's relation between filings and economic well-being is consistent with the general pattern of other High Courts. The area covered by the Gauhati High Court moved from extremely low filings per capita into the 1980s to a filings rate consistent with the mainstream by the 2005-2010 period,⁹⁵ as suggested by Figure 1A. Figure 7 shows that, by 1972, its GDP per capita was greater than or not materially different from that of several other High Court areas, a pattern that persists in the most recent time period, as Figure 6 shows. Gauhati may be a within-state instance of improved relative economic well-being over time leading to increased and more mainstream relative civil filings rates.

Delhi, India's national capital territory, has a persistently high outlying High Court filing rate in Figure 7. In his six-country study, Clark noted that high development is associated with a country's capital region.⁹⁶ His data showed that the countries' capital regions showed higher litigation rates than did other areas.⁹⁷ The Delhi High Court data are consistent with his predictions about a country's capital region.

Delhi's relative filing rates in the lower courts, as shown in Figures 2 and 3 and Table 2, are not subject to this straightforward explanation. Those data show that Delhi's lower courts filing rates have been lower than those of several other courts, such as Chandigarh and Goa which Figure 3 shows are also more prosperous than Delhi. When Chandigarh and Goa are grouped with other areas for purposes of High Court jurisdiction (Punjab & Haryana and Bombay, respectively), their economic prosperity relative to Delhi is diluted, they fall below Delhi (Figure 6) in prosperity and, at the High Court level, Delhi's High Court filing rate exceeds their rates.

But economic prosperity as measured by GDP per capita can be only a partial explanation for Delhi's varying rank in filings across High Courts and lower courts. Figure 3 shows that several areas that are less prosperous than Delhi (Himachal Pradesh, Kerala, Puducherry, Tamil Nadu) nevertheless have higher lower court civil filing rates. Kerala's higher filing rate may be a function of its well-being exceeding that of Delhi based on the HDI, as shown in Figure 5 and Table 2, or based on non-GDP measures of economic prosperity. Kerala has by far the highest life expectancy and lowest infant mortality of states for which the data are reported.⁹⁸ And consumer household expenditures in Kerala exceed those of other major states.⁹⁹ At the High Court level, Himachal Pradesh's filing rate exceeds Delhi's in

⁹⁵ But in 1969 its civil filings rate exceeded that of the Orissa and Patna (Bihar) High Court areas.

⁹⁹ National Sample Survey Office, National Statistical Organization, Ministry of Statistics and Programme Information, Govt. of India, *Level and Pattern of Consumer Expenditure 2009-2010*, at 22-23 (NSS 66th Round, NSS Report No. 538(66/1.0/1) Dec. 2011) (showing Kerala ranking first in rural consumer expenditures and second to Goa in urban consumer expenditures); National Sample Survey Office, National Statistical Organization, Ministry of Statistics and Programme Information, Govt. of India, *Household Consumer Expenditure in India, 2007-2008*, at 13 (NSS 64th Round, NSS Report No. 530(64/1.0/1) March 2010) (showing Kerala ranking first of major states in rural and urban consumer expenditures). Kerala's stronger performance as

recent years (Figure 6) even though its GDP per capita is less than half that of Delhi, as shown in Table 2. Note, however, that by the HDI well-being measure, Figure 5 and Table 2 show that Himachal Pradesh is not as far behind Delhi as by the GDP measure. And by at least one measure of poverty Himachal Pradesh's poverty rate is about two-thirds of Delhi's.¹⁰⁰

4. Within-State Changes in Litigation Rates and Prosperity

Parts IV.A.1 and IV.A.3 show cross-sectional associations between civil filings and prosperity across states. A natural further question is whether filings and prosperity move in the same direction within states over time. If filings and GDP growth were to move in opposite directions within a state, the possibility exists that the interstate filings-GDP association is an artifact of unobserved factors that vary across states that happen to be correlated with the factor we observe, GDP. Within a state, movement in the same direction cannot be attributable to unobserved factors that differ across states because the state being analyzed is held constant. Analyzing within-state change accounts for unobserved factors in a state that do not vary over time. The 1977 and 2010 lower court state-level filings and GDP data allow us to observe the association between changes in civil filing rates and changes in economic prosperity for two widely separated points in time within India's states. If the association between filings and prosperity exists, states with increased GDP should show increased filings and those states with greater change in GDP between the two years should show greater increases in filings per capita.

Figure 8 shows India's nominal GDP growth over time.¹⁰¹ Notwithstanding substantial inflation, real growth has been impressive. The rapid increase is usually attributed to economic reforms of the 1990s that included liberalized trade and reducing the size of the public sector.¹⁰² In the GDP measures used in this subsection, we adjust rupees so higher GDP values represent real, not nominal increases.¹⁰³ Analysis of change over time should also account for the decennial conduct of censuses. For example, using the 1981 Census to account for states' 1977 populations overstates their populations and therefore understates 1977 per capita filings. And using the 2011 Census for 2010 populations slightly understates 2010 per capita filings. In this subpart, we use linear interpolation to estimate 1977 and 2010 populations, which are

measured by household expenditures may relate to its high percentage of households receiving inflows from remittances outside of India. Devesh Kapur, *Diaspora Development and Democracy* 115-19 (2010).

¹⁰⁰ Guruswamy and Singh, *supra* note 31, at 285.

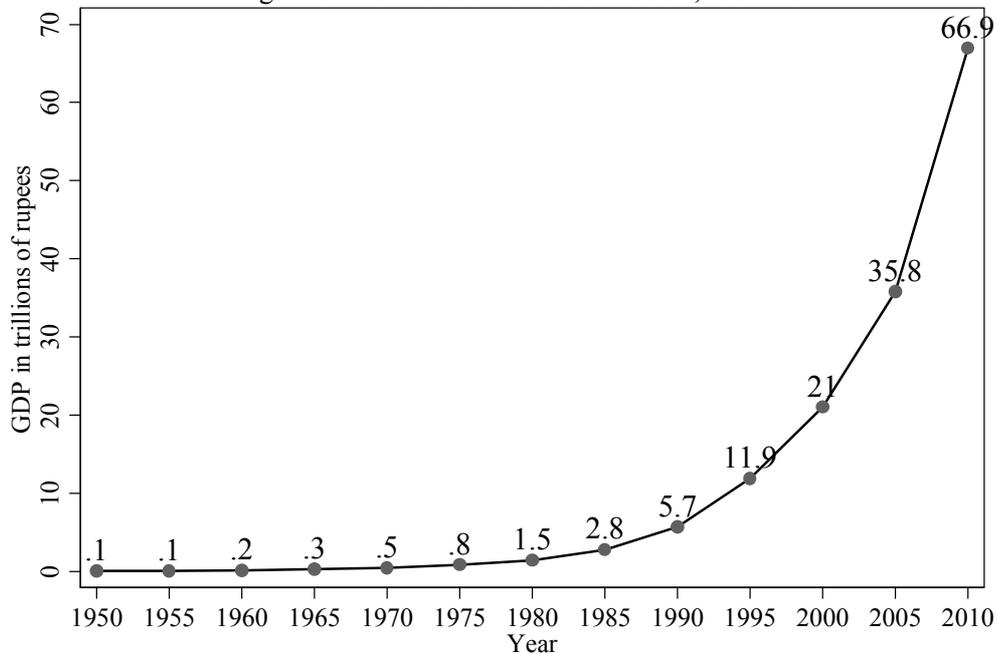

¹⁰¹ Growth consistent with Figure 8 emerges in the figures above by, for example, comparing the x-axis scales in Figures 6 and 7. Both use nominal rupees and the high end of Figure 7, which covers 2005 to 2010, requires a value of about 80,000 rupees per capita for the x-axis. The high end of Figure 6, which covers 1977, requires a value of between 4,000 and 5,000 rupees per capita, with most states concentrated below 2,000 rupees.

¹⁰² E.g., Devesh Kapur, *Explaining Democratic Durability and Economic Performance: The Role of India's Institutions*, in *Public Institutions in India: Performance and Design* 28-29 (Devesh Kapur & Pratap Bhan Mehta eds. 2005); Ashok Kotwal, Bharat Ramaswami & Wilima Wadhwa, *Economic Liberalization and Indian Economic Growth: What's the Evidence?*, 49 *J. Econ. Lit.* 1152, 1194 (2011) ("The sustained growth that we have seen since the mid-1990s would clearly not have been possible without the liberalizing reforms of 1991."). Kotwal et al. also state that "some aspects of the earlier economic regime played a positive role in the pattern of development later." *Id.*

¹⁰³ To adjust for inflation, we used the year to year changes in the December wholesale price index available in *Month-wise Variation in Inflation Annual Rate in India (1981 to 2011)*. These data are available at <http://www.indiastat.com..>

then used to compute per capita filings and GDP. We similarly adjust 1977 GDP because the data we used in the cross-section analyses was 1980 GDP per capita.

Figure 8. India Gross Domestic Product, 1950-2010

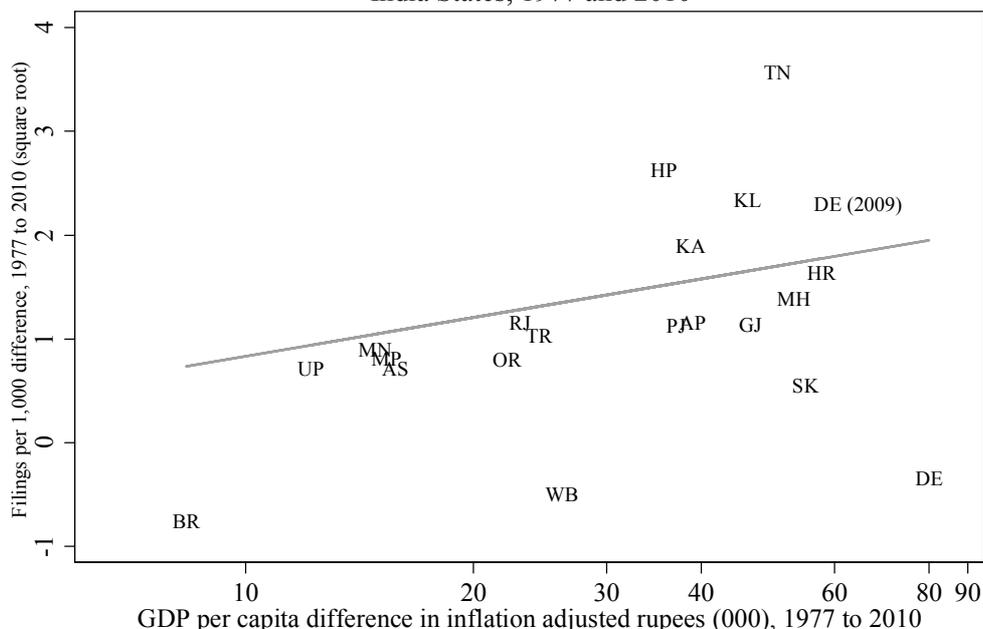

For each state, we compute the difference in filings per capita by subtracting the 1977 filings per capita from the 2010 filings per capita. Real GDP growth over time varies across states. By using GDP at the state level and using within-state change in its growth over time, we can partly control for varying state growth rates. We therefore compute the change in GDP by subtracting the state’s GDP in inflation-adjusted 1980 rupees¹⁰⁴ from the state’s GDP in 2010. Figure 9 shows the outcome. A sharp drop in the reported number of Delhi’s lower court filings from 2009 to 2010 led us to report two values for Delhi, one based on 2010 filings, the same end point year used for all other states, and one based on 2009 filings (with an accompanying shift to 2009 GDP data). The 2009 values are labeled “Delhi (2009)” in Figure 9 (and in Figure 10 below). Statistical results reported use the 2010 Delhi data.

Figure 9 shows two results of interest. First, all states show increased real GDP per capita (all x-axis values are positive) and all but three states, Bihar, Delhi (using 2010 data), and West Bengal, show increased filings per capita. A strong tendency therefore exists for GDP and filings to move in the same direction within a state. Second, the flow of the data points from lower left to upper right shows that the size of the filing increase within a state is associated with the size of the GDP increase in the state. States with larger GDP per capita growth had larger filing per capita increases. And the state with the largest filing decrease, Bihar, had the smallest GDP increase. In a regression model of the change in filings per capita as a function of the change in GDP per capita, the coefficient for the change GDP per capita is

¹⁰⁴ The 1977 state-level GDP we use was reported in 1980 rupees.

large and statistically significant.¹⁰⁵ The line shown in Figure 9 is the predicted line from a regression model. Comparing 1977 with recent years other than 2010 did not produce materially different results.

Figure 9. Change in Civil Filings as a Function of Change in GDP, India States, 1977 and 2010

Note. The figure shows the difference in filings per capita in lower courts from 1977 to 2010 as a function of the difference in GDP per capita for the same two years. Some states lacked data for both years and are not included. Filings per capita are shown on the y-axis using a variance-reducing square root transformation. For the three states with a filing decrease, the square root of the absolute value of the decrease was taken and then the sign restored to its negative status. Two data points are reported for Delhi due to the dramatic decline in filings reported from 2009 to 2010. Sources: India Sup. Ct. High Court News; Law Comm'n of India, Seventy Seventh Report; 1971, 1981 and 2011 Censuses; Directorates of Economics & Statistics of respective State Governments; Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India.

Does the within-state association between filing changes and GDP changes exist over a time period shorter than the 33 years between 1977 and 2010? To explore this, we repeat the within-state change analysis in Figure 9 but replace 1977 with the earliest recent year for which we have data, 2005, and compute filing and GDP differences between it and 2010.

Figure 10 presents the results, which differ strikingly from those in Figure 9. Real economic growth persists in all states; all of the real GDP differences on the x-axis are positive. But the changes in filings differ. Eleven of 30 states for which we have data for both

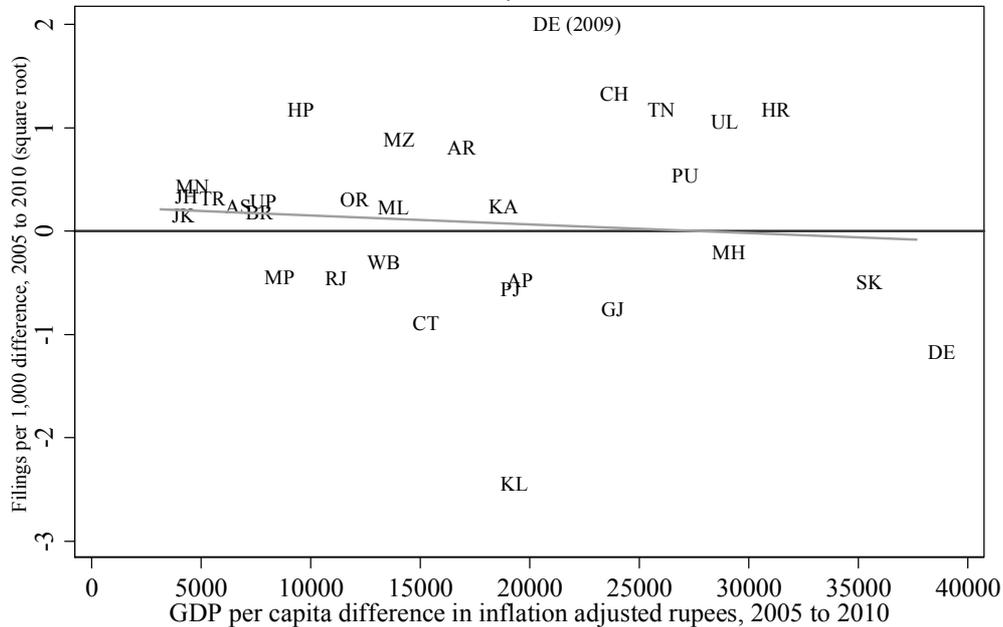

¹⁰⁵ Due to the heteroskedasticity apparent in the scatterplot, we employed weighted least squares regression with weighting based on the difference in GDP per capita (log). Because the dependent variable benefitted from a square root transformation and had two negative values, we added a small constant to each observation to assure only positive values before the transformation.

years (all those falling below the horizontal “0” line in the figure) show reduced filings per capita in 2010 compared to 2005. Several others show no material increase. Our data allow us to compute the differences in filings within states for 146 state-year observations from 2005 to 2010, 71 of which showed a decline in filings in the subsequent year. So, despite broad economic growth, about half of the possible state-year observations showed declining civil filings per capita. In an analysis not shown here, the same pattern exists for High Court cases from 2005 to 2010.¹⁰⁶ Figure 8 shows that the period 2005 to 2010 was one of substantial GDP growth for India. So an association between GDP growth and filings growth had a reasonable opportunity to emerge, yet did not. Large GDP growth was not accompanied by filings growth within many states.

Some of the more extreme changes from 2005 to 2010 may be artifacts of the particular years used. Kerala’s large filing decrease in Figure 10 is sensitive to the choice of year because 2005 was a year of extraordinarily high reported filings for it compared to any subsequent year. Filings in 2005 were at least 69 percent higher than in any subsequent year. This spike may lead to an overstatement of Kerala’s 2005 filing rate and of the decline from 2005 to 2010. As already noted, Delhi’s filings also fluctuate substantially in the 2005 to 2010 period. Mizoram’s filings in 2005 are reported to be 25 compared to 2,369 in 2010 and substantial variation exists for Arunachal Pradesh. So the most extreme data points in Figure 10 are likely also the most questionable. The overall pattern, however, is one of no systematic increase. The sloping line in the figure is the line predicted by a regression model of filings change as a function of GDP change. The slope is nearly flat, statistically insignificant, and, if anything, shows a negative association between GDP change and filings change.

¹⁰⁶ Interestingly, there is substantial growth in Supreme Court civil filings during this same period (2005-2010). 33,715 civil cases were filed in the Supreme Court in 2005. 51,709 civil cases were filed in the Supreme Court in 2010. Annual Statement of the Indian Supreme Court 2005 and 2010. However, this increase in filing likely has little to do with an increase in prosperity during this time period. Instead, this marked increase is more likely a sign that litigants increasingly view appeal to the Supreme Court favorably for other reasons. This may be because Supreme Court precedent is becoming less clear, making appeal a more successful strategy, or because appeal is becoming a more favored tactic for delay.

Figure 10. Change in Civil Filings as a Function of Change in GDP, India States, 2005 and 2010

Note. The figure shows the change in filings per capita in lower courts from 2005 to 2010 as a function of the change in GDP per capita for the same years. For states with a filing decrease, the square root of the absolute value of the decrease was taken and then the sign restored to its negative status. Due to Mizoram's implausibly low filings reported in 2005, the figure uses the 2006 to 2010 differences for that state. Two data points are reported for Delhi due to the dramatic decline in filings reported from 2009 to 2010. Sources. India Sup. Ct. High Court News; 2001 and 2011 Censuses; Ministry of Statistics and Program Implementation; Press Information Bureau, Govt. of India.

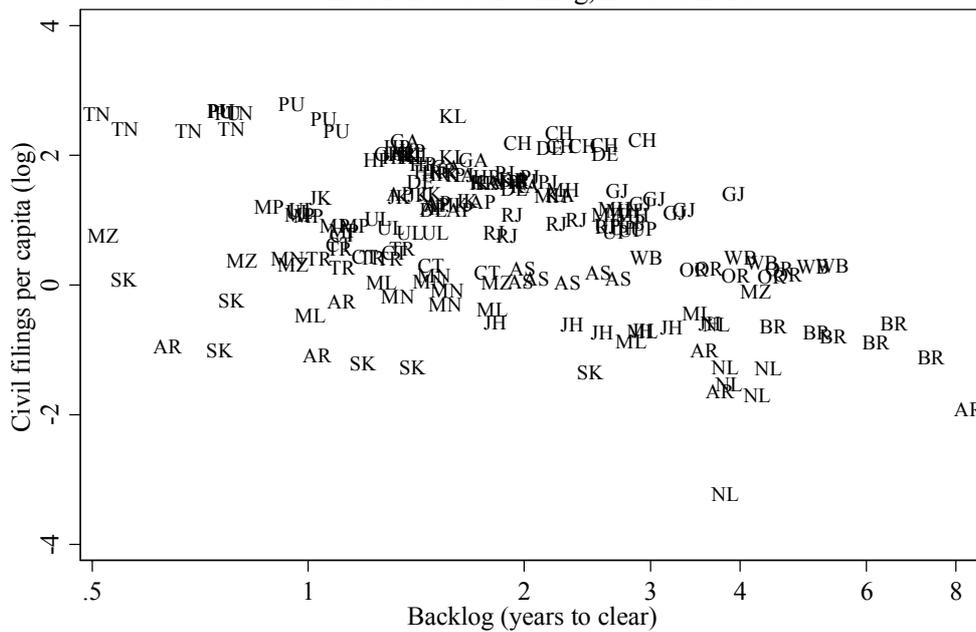

5. Filings Rates and the Case Backlog

Growing concern exists in India that people forego using the courts because of the large backlog of cases.¹⁰⁷ So the absence of within-state association between changes in filing rates and GDP change in recent years could be associated with India's case backlog. That backlog has increased substantially over recent decades. In 1977 the ratio of pending lower court civil cases to filings was 1.48; by 2010 it had grown to 1.90, an increase of about 28 percent. The interstate associations using lower court and High Court data, and the within-state changes, as measured by the 2010 and 1977 differences, suggest that changes in GDP do influence filings. But that process may break down in a court system that processes cases insufficiently. The early 21st Century may be the time at which litigants in greater numbers responded to the expected delay by declining to file cases. Figure 10's absence of association may be evidence of that process. We therefore analyze in more detail the relation between filings and case backlog.

¹⁰⁷ Hazra & Debroy, *supra* note 66; Hazra & Micevska, *supra* note 37, at 149; Kasturi, *supra* note 60.

Figure 11 shows the relation between states' civil filings per capita and their civil case backlogs for each state for each year from 2005 to 2010. The data flow from upper left to lower right, suggesting that increasing backlog is associated with decreasing filings. The trend is highly statistically significant, with a correlation coefficient of -0.43 and a significance level of $p=0.004$.¹⁰⁸ In recent years, therefore, the individual state-year observations show a strong negative association between backlog and filings.

Figure 11. Relation Between Lower Court Civil Filings Per 1,000 and Civil Case Backlog, 2005 to 2010

Note. The figure shows civil filings per capita in lower courts from 2005 to 2010 as a function of the backlog for the same years. The relation is shown for each state for each year. Due to Mizoram's implausibly low filings reported in 2005, the figure includes data for Mizoram only for the years 2006 to 2010. x axis scale is in logs. Source. India Sup. Ct. High Court News; 2001, 2011 Censuses.

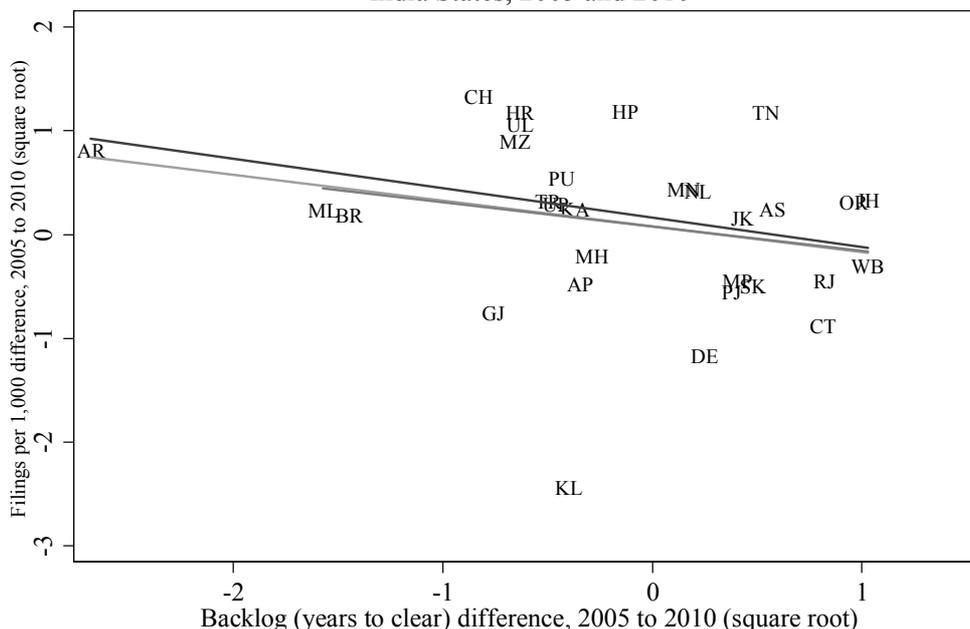

As in the case of the filings-GDP relation, a natural further inquiry is the relation between filings and backlog within states over time. If the negative association between filings and backlog suggested by Figure 11 persists within states, those states with increased backlogs over time should show decreased filings over time. Figure 12 shows the filing change-backlog change relation in the same manner that Figure 10 shows the filing change-GDP change relation. Figure 12, unlike Figure 10, shows a noticeable association. In other words, increasing backlogs are associated with decreasing filings.

The lines in Figure 12 represent the predicted values from three regression models. The uppermost line shows the predicted change in filings if Kerala (KL), an outlier with

¹⁰⁸ This significance level is based on a regression with filings as the dependent variable, backlog as the explanatory variable and standard errors clustered by state.

respect to the change in filings, is excluded. The shortest line, barely distinct from the longer line adjacent to it, shows the predicted change in filings if Arunachal Pradesh (AR), an outlier with respect to backlog reduction, is excluded. The remaining line, beginning near the AR datapoint, includes all states. The significance of the relation varies depending on the treatment of outliers but it is consistently significant at the 0.10 or 0.05 levels.¹⁰⁹ The figure shows that the relation is consistently negative regardless of outlier treatment. Comparing Figure 12's noticeable trend with Figure 10's absence of relation suggests that backlog variation has recently had a greater influence on filing change than has GDP variation.

Figure 12. Change in Civil Filings as a Function of Change in Backlog, India States, 2005 and 2010

Note. The figure shows the change in filings per capita in lower courts from 2005 to 2010 as a function of the change in the backlog for the same years. For states with a filing or backlog decrease, the square root of the absolute value of the decrease was taken and then the sign restored to its negative status. Due to Mizoram's implausibly low filings reported in 2005, the figure uses the 2006 to 2010 differences for that state. The lines in the figure are predicted values from regressions that account for outliers as described in the text. Sources. India Sup. Ct. High Court News; 2001 and 2011 Censuses.

B. Regression Results

¹⁰⁹ In a regression model with robust standard errors that includes all 30 states in the figure, the significance of the filings change-backlog change association is $p=0.029$. If one excludes Kerala and Arunachal Pradesh, the significance level is $p=0.065$. If one excludes only Kerala, the significance level is $p=0.012$. If one excludes only Arunachal Pradesh, the significance level is $p=0.166$. So only by including Kerala but not Arunachal Pradesh is the significance level greater than 0.10. In a robust regression model that automatically assigns less weight to outlying values but includes all of them, the significance level is $p=0.098$.

Part IV.A assessed influences on filings separately from one another and suggested associations between filings and: (1) GDP, (2) population density, (3) the HDI, (4) backlog. In recent years, however, change in GDP had no association with change in filings, as shown in Figure 10. To further assess the relations between civil filings and the other factors, we employ regression models in which the rate of civil filings per capita is the dependent variable. Preliminary inspection of the data, as suggested by several of our figures,¹¹⁰ indicated that transformations of variables were needed,¹¹¹ so the models use logarithmic transforms for continuous variables other than the HDI. The explanatory variables are GDP per capita (log), population density (log), the HDI, and the backlog, measured as years to clear (log). We add to the models dummy variables for the years 2006 to 2010, with 2005 serving as the reference category. These dummy variables help account for unobserved characteristics in each year. Since we observe the same geographic units, states, repeatedly over time, we cluster the standard errors by state. Table 3 reports the regression results.

Table 3. Regression Models of Civil Litigation Filing Rates

R-squared	0.411	0.662	0.582	0.709	0.597	0.795	0.709

Note. HDI=Human Development Index. The table reports ordinary least squares regression models with state-years from 2005 to 2010 as observations. The reference category for year dummy variables is 2005. Data are missing for Goa for 2005, 2006, for Nagaland for 2010, for Tamil Nadu for 2009, and for West Bengal for 2007. Standard errors clustered on state are in parentheses. * p<0.01, ⁺ p<0.05, [#] p<0.1

The regression results both confirm and illuminate the bivariate results in Part IV.A. We discuss each of the major effects separately.

¹¹⁰ Note that in all figures in which the volume of filings (in contrast to the change in filings over time within a state) is represented on the y-axis, the filings are reported in logs.

¹¹¹ E.g., Sanford Weisberg, *Applied Linear Regression* 148-50 (3d ed. 2006); Theodore Eisenberg & Martin T. Wells, *The Significant Association Between Punitive and Compensatory Damages in Blockbuster Cases: A Methodological Primer*, 3 *J. Empirical Legal Stud.* 175, 179-81 (2006).

The GDP and Backlog Effects. Focusing first on model (1), the coefficient for GDP per capita is substantial and statistically significant. So, while accounting for population density, GDP is positively associated with filings per capita. This association persists in model (5), the only other model reported that used the full set of state-years. It differs from model (1) only in that it adds the backlog as an explanatory variable. The GDP coefficient remains significant in all other models as well, which are included to account for the effect of the HDI and backlog. The backlog's large and statistically significant coefficients in models (5) to (7) confirm the filings-backlog association suggested by Figure 11.

The GDP-Backlog Relation. The backlog's significance persists in models that include GDP as an explanatory variable. This suggests that the backlog's effect on filings is not solely due to GDP influencing the backlog through GDP's direct effect on filings (which increases the backlog). If it were, the backlog-filings association should not persist when GDP per capita is accounted for simultaneously with backlog. The association between GDP and the backlog would introduce substantial multicollinearity into the model which would deflate the importance of one or both variables.¹¹² Yet both variables remain statistically significant and a test of multicollinearity shows it not to be a substantial concern.¹¹³ In recent years, backlog's effect is increasing in importance over GDP's effect, as suggested by comparing the relations between changes in them to changes in filings illustrated in Figures 10 and 12. Furthermore, in regression models (not reported here) of the within-state *change* in filings per capita from 2005 to 2010 as a function of the changes in GDP per capita and changes in case backlog for that period, we find some evidence of a negative association between filings change and backlog change, as noted in our discussion of Figure 12 above, and no evidence of a positive association between filings change and GDP change. In recent years, changing backlog more than changing GDP has driven within-state changes in filings.

The HDI Effect. Figure 5 suggests that noneconomic well-being, as represented by life expectancy and education included in the HDI, is associated with litigation rates. We therefore include the HDI as an explanatory variable in three regression models, (2), (4), and (6). Since the HDI is not available for several states (see Table 2), fewer observations are available for those models than for models (1), (3), and (5). But note that the states excluded for want of HDI data are uniformly small, with a total population of about 16 million people, less than two percent of India's population.

Model (2) is the same as model (1) except that the HDI replaces GDP per capita as an explanatory variable. To assure a common sample of states for purposes of comparing the effects of the HDI and GDP, model (3) repeats model (1) but limits the sample to those states included in model (2). So models (2) and (3) use the same sample of states and differ only in that model (2) uses the HDI and model (3) uses GDP per capita instead. As measured by the

¹¹² Some evidence of the variables experiencing reduced significance exists. The coefficient for GDP is much smaller in model (5) than in model (1). And, in a model not reported here, the coefficient on backlog is larger in absolute value (-1.06) in a model that is the same as model (1) except with backlog replacing GDP. So both GDP and backlog are of reduced influence when appearing in models together rather than separately. They are nontrivially correlated.

¹¹³ The average variance inflation factor (vif) for model (5) is 1.62, suggesting no substantial presence of multicollinearity. See Alan C. Acock, *A Gentle Introduction to Stata* 263 (3d ed. 2010). GDP has a vif of 1.56, suggesting that 1/1.56, or 64 percent of the variance in GDP is available after adjusting for the other predictors. Id. Backlog has a vif of 1.15 suggesting even less of an issue with respect to it.

proportion of the variance in the dependent variable explained by the model (the r-squared row in Table 3), model (2) substantially outperforms model (3).¹¹⁴ Model (4), again using the reduced sample, includes both the HDI and GDP and both remain highly significant. The model with both variables substantially outperforms the models with only one of them, models (2) and (3), with another substantial improvement in the proportion of variance explained. Multicollinearity is a greater concern here because the HDI includes an express economic component which should correlate with GDP. A test of multicollinearity, however, suggests that it is not a substantial concern.¹¹⁵ So while GDP per capita is an important factor in explaining litigation rates, noneconomic well-being also has a substantial role to play. If one had to choose between the HDI and GDP, the HDI produces superior models.¹¹⁶ In models not reported here, the HDI outperforms literacy when they are included in models separately and the coefficient on literacy is not significant when they are included in models together.

The Population Density Effect. The population density coefficient varies across models. It is positive and significant in models (1) and (5), which include the states that lack HDI information. But it is negative in the models that exclude those states and is statistically significant in some of those models but not in others. This variability is likely because the states lacking HDI information include many with the most extreme population densities. The six least densely populated states (see Table 2) lack HDI information. Chandigarh and Puducherry lack HDI information and are two of the three most densely populated areas. So including the HDI as an explanatory variable substantially reduces the variation in population density across states in the models. Since population density is significant when the full sample of states is available (in the models that do not include the HDI), population density cannot be ruled out as a significant influence on litigation rates notwithstanding its insignificance in models (6) and (7), and its marginal significance in model (3).

One concern about regression models that include the backlog as an explanatory variable is the presence of endogeneity or reciprocal causation,¹¹⁷ which makes ordinary least squares regression results questionable.¹¹⁸ Backlog may influence civil filings but the volume of past filings and the past backlog clearly influence the backlog. To address this concern, we have explored simultaneous equations models that simultaneously model civil filings and the

¹¹⁴ Another way to compare models using the same data, the same dependent variable, but differing explanatory variables is the root mean squared error, which measures how far a model's predicted values differ on average from observed values. The root mean squared error in model (3) is 0.56 compared to 0.50 in model (2) and 0.47 in model (4). So by this measure as well the models that include the HDI outperform the models without it. The Akaike information criterion also indicates that models that include the HDI fit the data better than those without it.

¹¹⁵ The average vif for explanatory variables in this model is 2.13, with GDP having a vif of 3.18. Note that the size of the GDP coefficient in model (4) is smaller than its size in model (3), suggesting that some of GDP's explanatory power is absorbed in the HDI. Similarly, the size of the HDI coefficient is smaller in model (4) than in model (2). Nor is multicollinearity a substantial concern in model (6), with an average vif of 2.14.

¹¹⁶ In a model using standardized coefficients, the HDI coefficient is 54 percent larger than the GDP coefficient. For information about a factor analysis that includes the HDI and GDP, see note 126 *infra*.

backlog and allow the number of filings in a prior year to influence the backlog.¹¹⁹ The results do not materially differ from those reported here.¹²⁰

V. Conclusion

The positive association between civil litigation and well-being should be reasonably interpreted. It does not imply that filing more lawsuits will increase societal well-being.¹²¹ Causation almost certainly runs in the opposite direction, with increased well-being leading to more lawsuits. The positive association is consistent with the law and development theorists' view that the modernization of a country increases reliance on formal institutions. It is also consistent with the overlapping account that states with higher GDPs have more transactions per capita. So, even if the litigation rate per transaction is constant over time, there will be more disputes per capita and therefore more lawsuits per capita.¹²²

An economic boom could conceivably decrease filing because prosperity may lead to more "forgiving behavior" given that the costs of going to court may be higher than simply just engaging in other economic activity.¹²³ Our results suggest that the factors underlying increased litigation rates outweigh this potential effect. Alternatively, times of economic decline might also be associated with increasing litigation rates.¹²⁴ For example, a declining economy is associated with more debt collection and bankruptcy filings,¹²⁵ which might dwarf the negative effect on filings of economic decline. Given the consistent economic growth in India shown in Figure 8, we cannot assess how a declining economy may impact litigation rates in India.

To our knowledge, the influence of noneconomic well-being on litigation rates has not heretofore been assessed. The fact that higher litigation rates are associated with Indian states with higher HDI indices suggests that people are more likely to use the courts to resolve disputes when they are economically, socially, and physically better off. Higher GDP is also correlated with higher litigation rates, but less so than the HDI index.

The HDI's explanatory superiority is likely due to it having both an economic component, income per capita, and a noneconomic component, including education level and life expectancy components.¹²⁶ Our findings may suggest that part of the increase in litigation

¹¹⁹ The structural equations in those models are the same as those in Table 3. The equation modeling the backlog uses one year lagged filings and the one year lagged backlog as explanatory variables.

¹²⁰ Serial correlation in the dependent variable does exist and we have run autoregressive conditional heteroskedasticity models, commonly known as ARCH models, as a further check. They yield results consistent with those in Table 3. In models with random effects for states, the coefficients for HDI and backlog remain highly statistically significant and the coefficient for GDP per capita is marginally significant. For an effort to address similar correlation in backlog models, see Hazra & Micevska, *supra* note 37, at 150-52.

¹²¹ At the individual level, the outcome of a lawsuit may increase personal well-being.

¹²⁶ The HDI outperforms models in which its use as an explanatory variable is replaced by both GDP per capita and literacy rates. In models that include both the HDI and literacy rates as explanatory variables the coefficient for literacy rates is insignificant. We have also explored models that include state level poverty rates, which are

rates in higher HDI states is driven by individuals with increased education or life expectancy. These individuals may file claims in personal disputes or small commercial disputes. The implications for those who are concerned about the fact that many Indians lack access to justice and courts is that simply improving the courts or macroeconomic growth are not the most important factors in ensuring that people are able to assess the courts. Indeed, guaranteeing access to justice, which includes providing individuals with a realistic chance to vindicate rights through litigation may require governments to ensure economic opportunity and social rights to individuals. GDP growth alone does not assure all individuals a realistic opportunity to vindicate rights.

Another result, which is somewhat surprising, is that filings in recent years, reported in Figure 10, do not increase with increasing prosperity. The leveling off theory referred to in Part I might be considered as a source of this result. If India has reached a plateau, however, its filings are leveling off at levels well below filings in more prosperous countries. Despite India's impressive recent growth its overall prosperity remains at modest levels with respect to basic measures such as GDP per capita and the HDI. One mechanism for the plateau being reached also seems absent. Sarat and Grossman argued that as society becomes more developed, courts become specialized so that the generalist courts lack the expertise to resolve disputes. Although India has some recent movement in the area of specialized dispute resolution tribunals, that movement is likely insufficient to explain the severing of the relation between economic growth and litigation growth.¹²⁷

A more likely explanation for the absence of association between GDP change and filing change in recent years is high and increasing backlog, as suggested by Figures 11 and 12 and Table 3. Increased backlog was significantly associated with reduced filings per capita. This finding resonates with qualitative beliefs about backlog's effect, as well as with one earlier effort to quantify the effect.¹²⁸ This explanation also has intuitive appeal. Figure 11 and Table 2 show that backlogs in many states exceed two years, even assuming no new filings, and the 1977 data establish that backlogs have increased over time in relation to filings. It would not be surprising if, at some point, potential litigants turn away from courts for dispute resolution as a result. India may have reached that point.

India's challenge is not that too many cases are filed but that too few are timely adjudicated. Its litigation rate, by world standards, is not high. The judiciary, though in increasing demand as the country prospers, could threaten India's prosperity if it cannot accommodate demands for its services. India thus may provide a test of theories that a well-functioning court system is critical to economic growth.¹²⁹ Its lower court system continues to

also significantly correlated with litigation rates. Models using the HDI outperform those using poverty rates in its place. In models that include both the HDI and poverty rates as explanatory variables the coefficient for literacy rates is insignificant. In models that included the HDI, literacy rates, and poverty rates, multicollinearity leads to unreliable coefficient estimates. We used poverty rates reported in Guruswamy & Singh, *supra* note 31, at 285. Factor analysis (principal factor) suggests that only one principal factor is at work among these explanatory variables, with a much less important second factor also at work. The HDI loads most strongly on the first factor and the poverty rate loads most strongly on the second factor.

be regarded as dysfunctional and we provide evidence that the backlogs now discourage use of the courts.¹³⁰ It should be noted that the backlogs may be caused not principally because of slow case processing by judges, but by the fact that there may not be enough courts allotted or because of the large number of vacancies that currently exist. In addition to the increasing backlog in Indian courts, other factors that have not been tested in this paper could also account for decreasing litigation rates such as corruption, which, among other problems, leads to lack of predictability in the system. Additionally, many judges, especially in the lower judiciary lack proper infrastructure and implements such as computers or typewriters to undertake their work. Despite this, the country has undergone substantial growth. Whether that growth can continue will yield important information about the need for a well functioning judiciary to promote well-being.

India's civil filings story has implications beyond its borders. The anti-litigation movement in the U.S. and elsewhere is built in part on characterizing litigation as evidence of social malfunction. Evidence from India and elsewhere that increased litigation often accompanies improved human well-being should be considered when evaluating the social implications of the amount of litigation.
